# Links in Large Integrated Knowledge Graphs: Analysis, Refinement, and Domain Applications

Shuai Wang

**ORCID:** 0000-0002-1261-9930

**Date:** 17 December 2025

# Motivation

- In my thesis, I studied knowledge graphs that are linked data. Data graphs are excluded.
- Integrating knowledge graphs of linked data published on the semantic web can result in (inherited) errors.
- Previous work showed that errors could be amplified in graphs due to the logical properties.
- The semantics in knowledge graphs imply structural properties (e.g., class subsumption), vice versa.
- Example: graphs corresponding to transitive, asymmetric, and irreflexive relations should not have cycles at all.

# Research Question

How can we take advantage of the graph structure of large integrated knowledge graphs for their analysis and refinement?

# Research Question

How can we take advantage of the graph structure of large integrated knowledge graphs for their analysis and refinement?

scalability

graph theory

redundancy

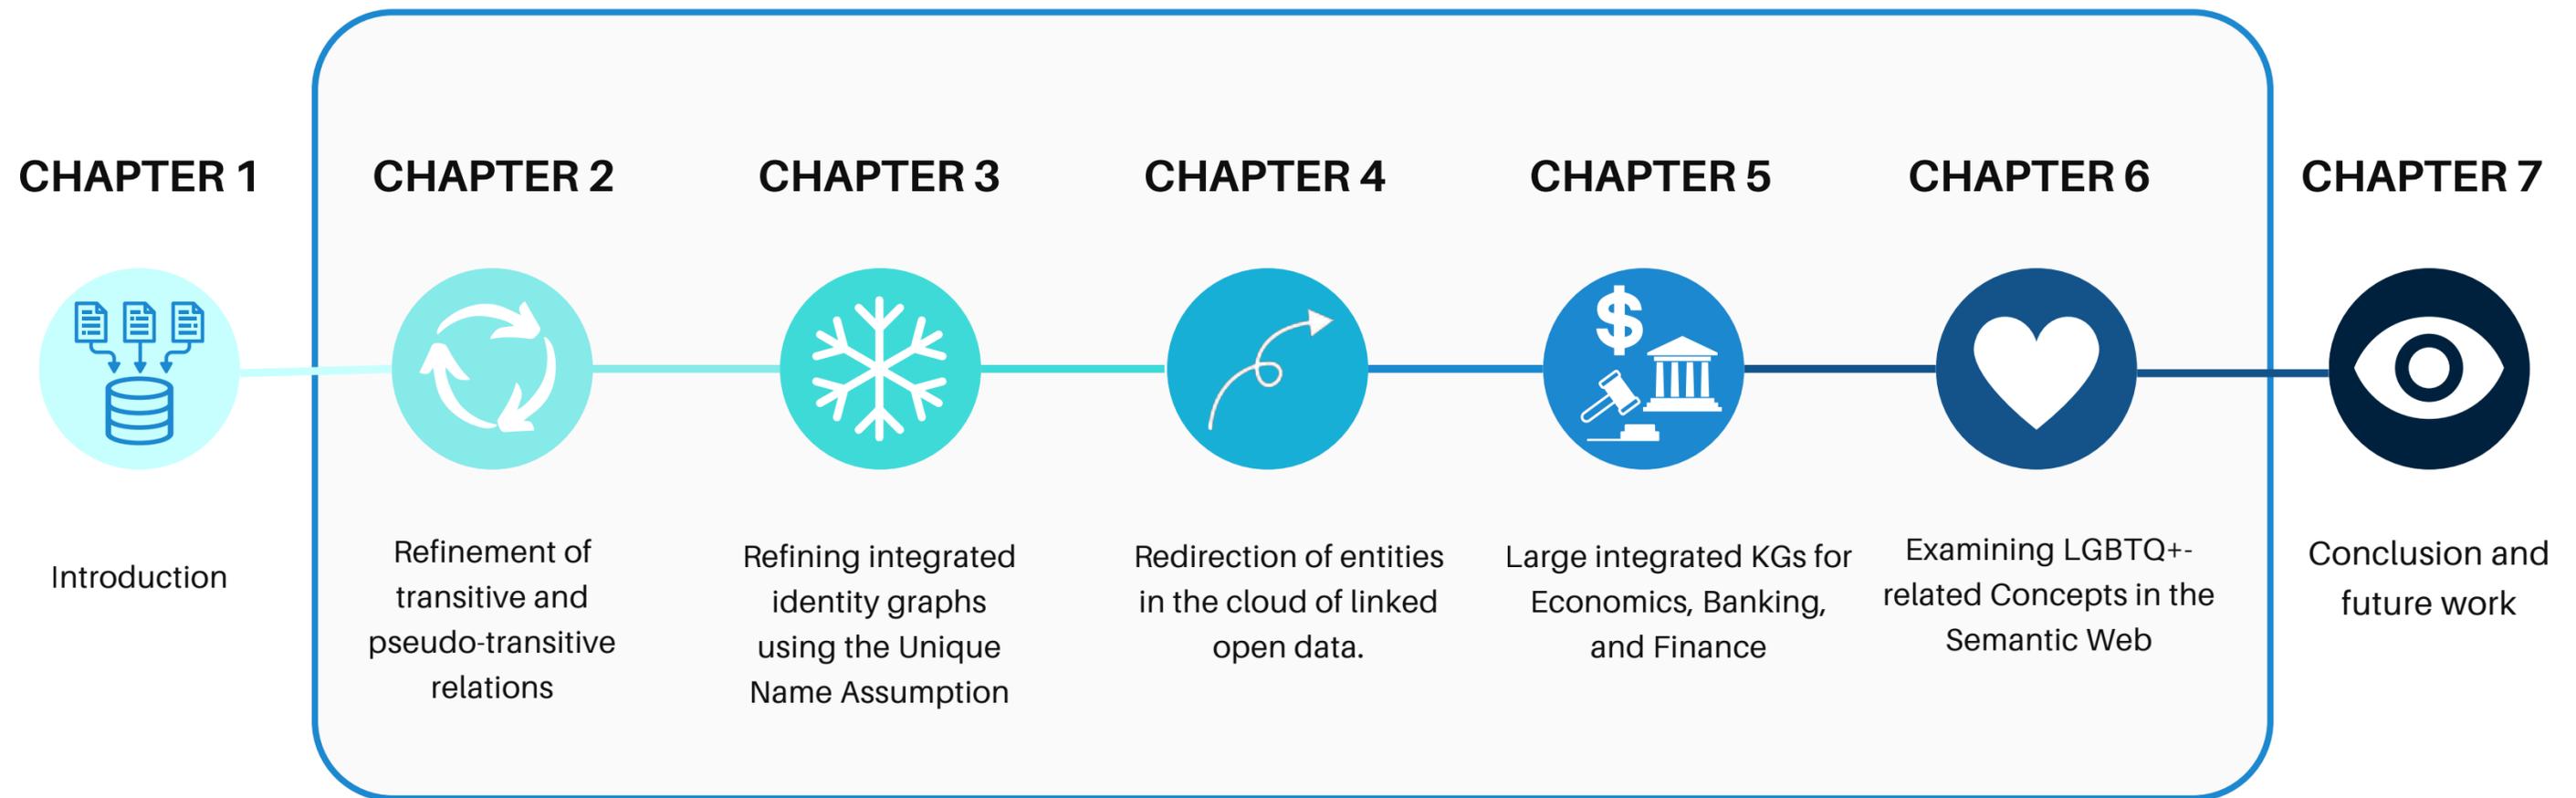

semantics

evolution

metrics  
and  
indicators

domain applications

# Thesis Outline

# Ch2: Transitive and (Pseudo-)transitive relations

- (Pseudo)transitive relations
- Complex nested cycles (LOD-a-lot)
- An algorithm to make knowledge graphs acyclic
- preserving as much information as possible
- Multilingual, no reference to textual info, etc.

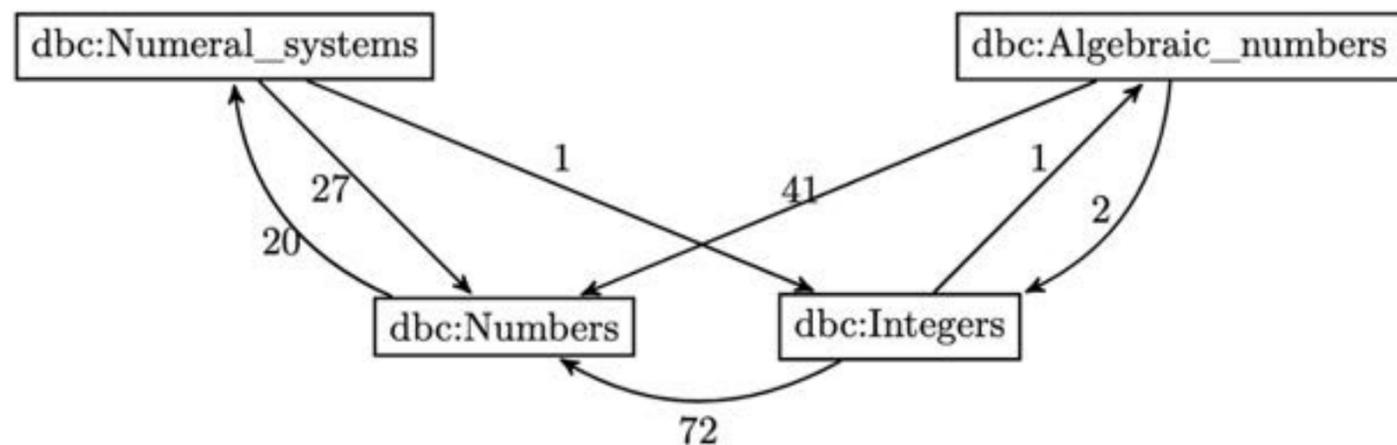

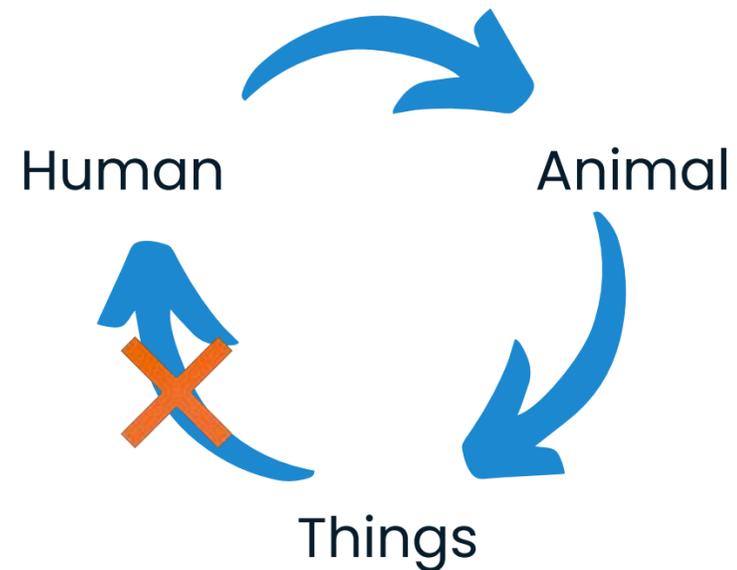

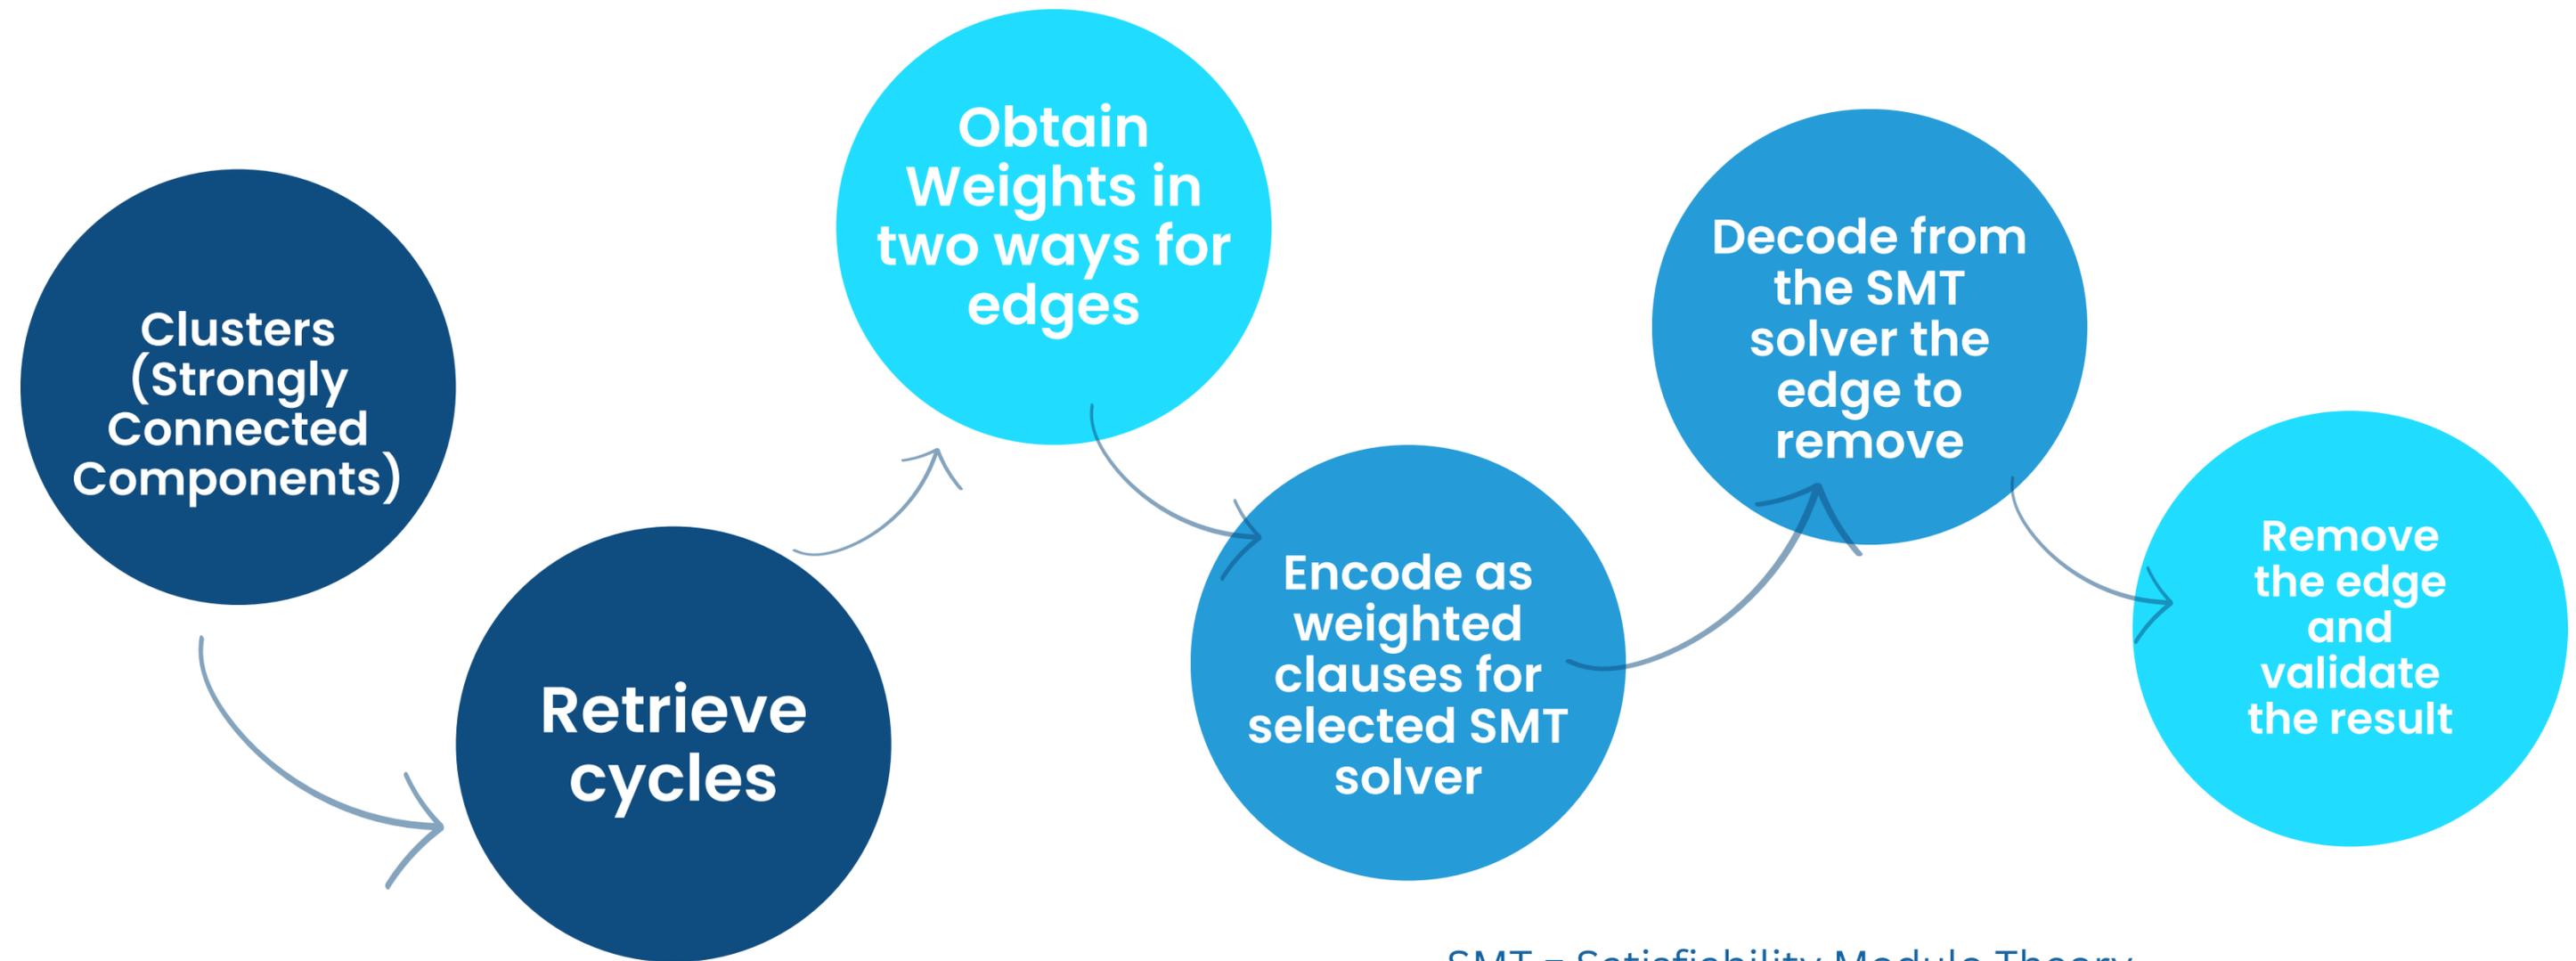

Figure 6: An example subgraph of `skos:broader` with weights.

|                           | <code>rdfs:subClassOf</code> | <code>skos:broader</code> |
|---------------------------|------------------------------|---------------------------|
| Type                      | Transitive                   | Pseudo-Transitive         |
| #Edges                    | 4.4M                         | 11.8M                     |
| #Nodes                    | 3.6M                         | 5.7M                      |
| #Nodes in the Largest SCC | 837                          | 82K                       |
| #Edges in the Largest SCC | 1.4K                         | 365.9K                    |

SMT = Satisfiability Modulo Theory

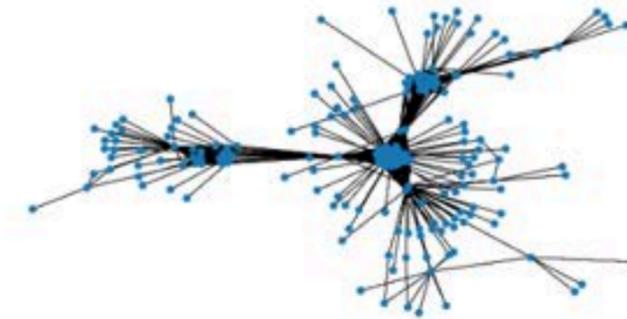

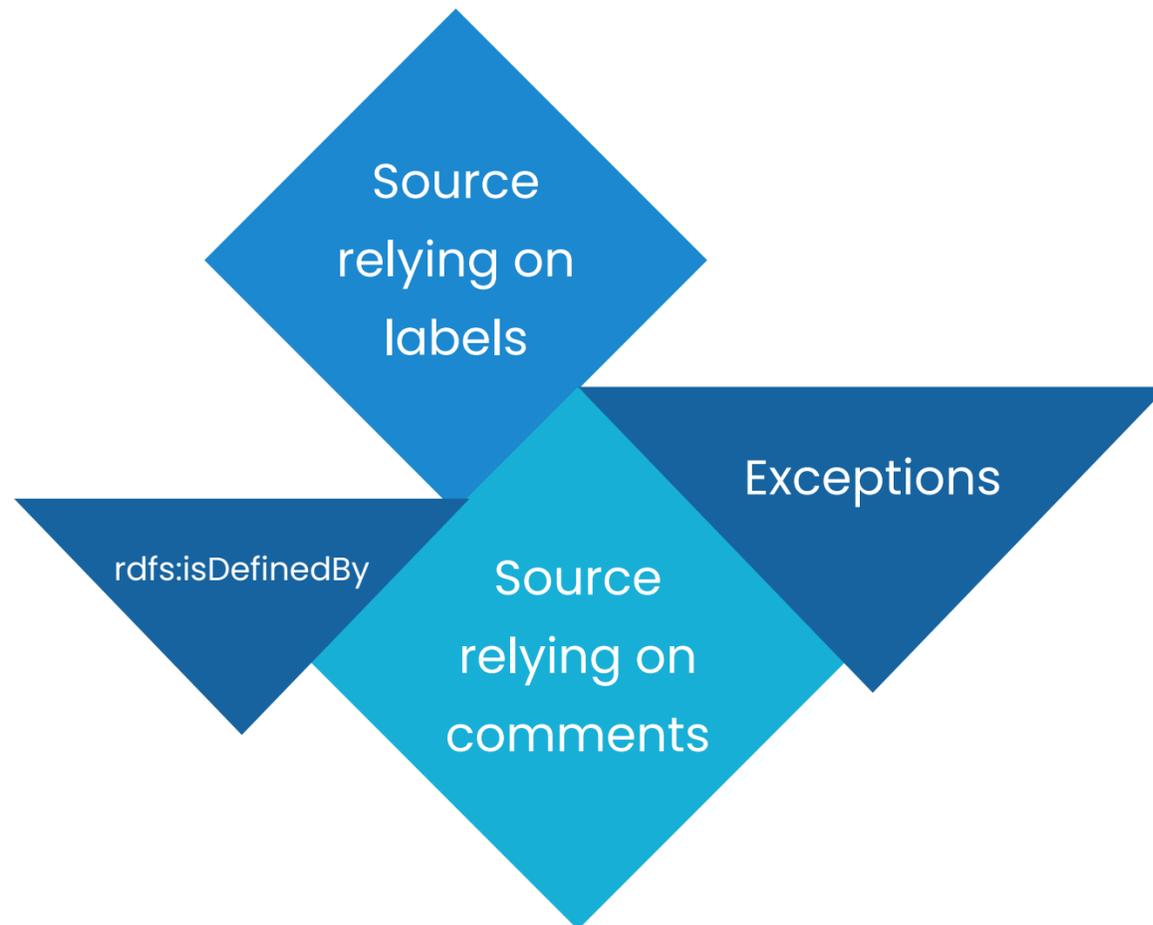

Algorithm Design

# Ch3: Identity Graphs & Unique Name Assumption

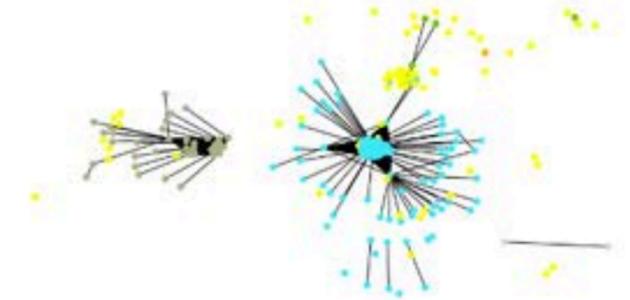

nUNA

qUNA

iUNA

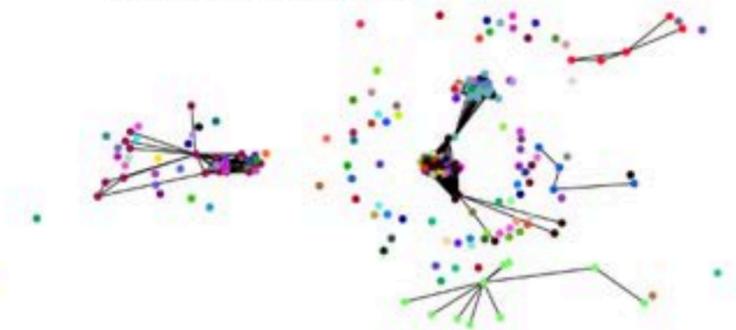

(a) An example CC with 633 nodes

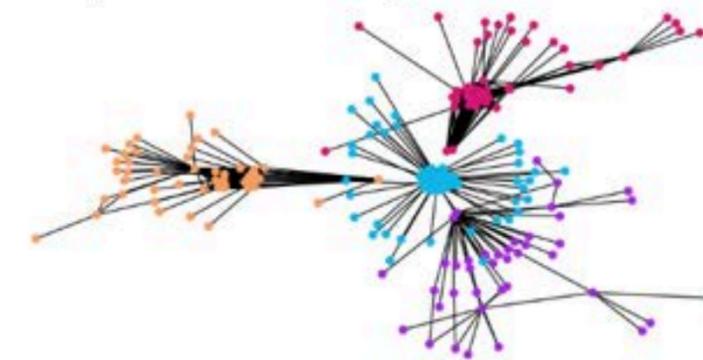

(b) Its gold standard without erroneous edges (yellow nodes are those labeled 'unknown')

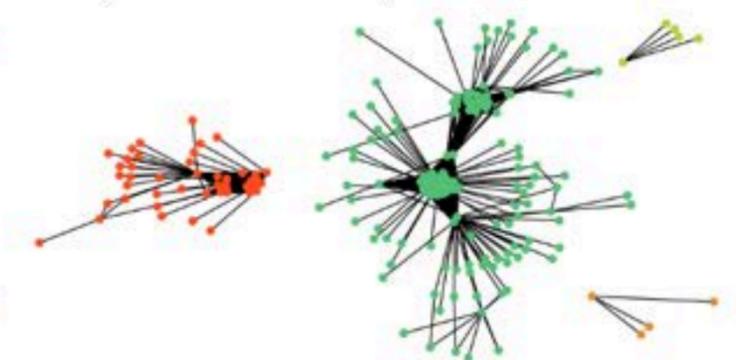

(c) A solution by the Louvain method (resolution = 0.01)

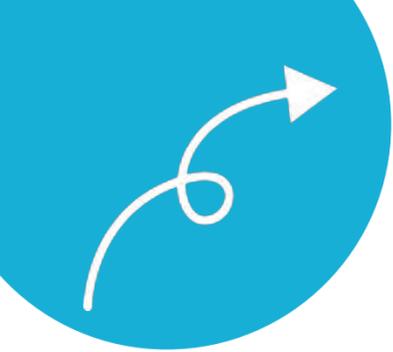

(d) A solution by the Louvain method (resolution = 1.0)

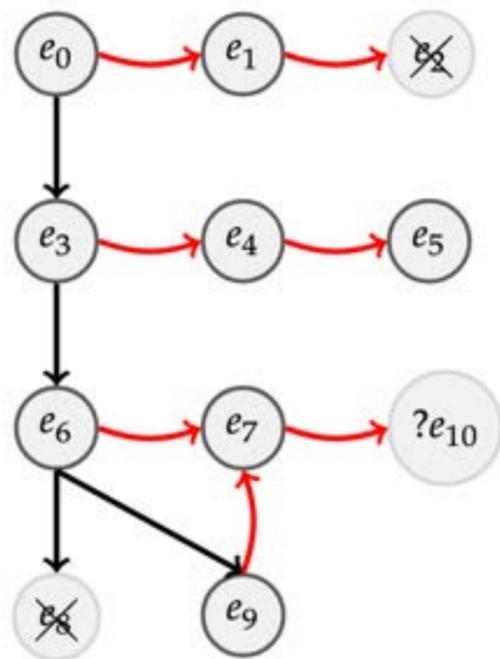

(e) A solution by the Leiden method

(f) A solution by our algorithm

# Ch4: Examining the Evolution of Entities through Redirection

- Not found (HTTP 400+)
- Timeout
- Redirected until not found
- Error
- ...

- Outdated resources are typically redirected to new locations (19.4% of entities no longer exist on the web after 2 years).
- Semantics in redirect?
- 38–53% of entities are redirected. Redirection chains can involve as many as 9 entities.
- Estimate that between 45.1% and 83.2% of such links can preserve identity.

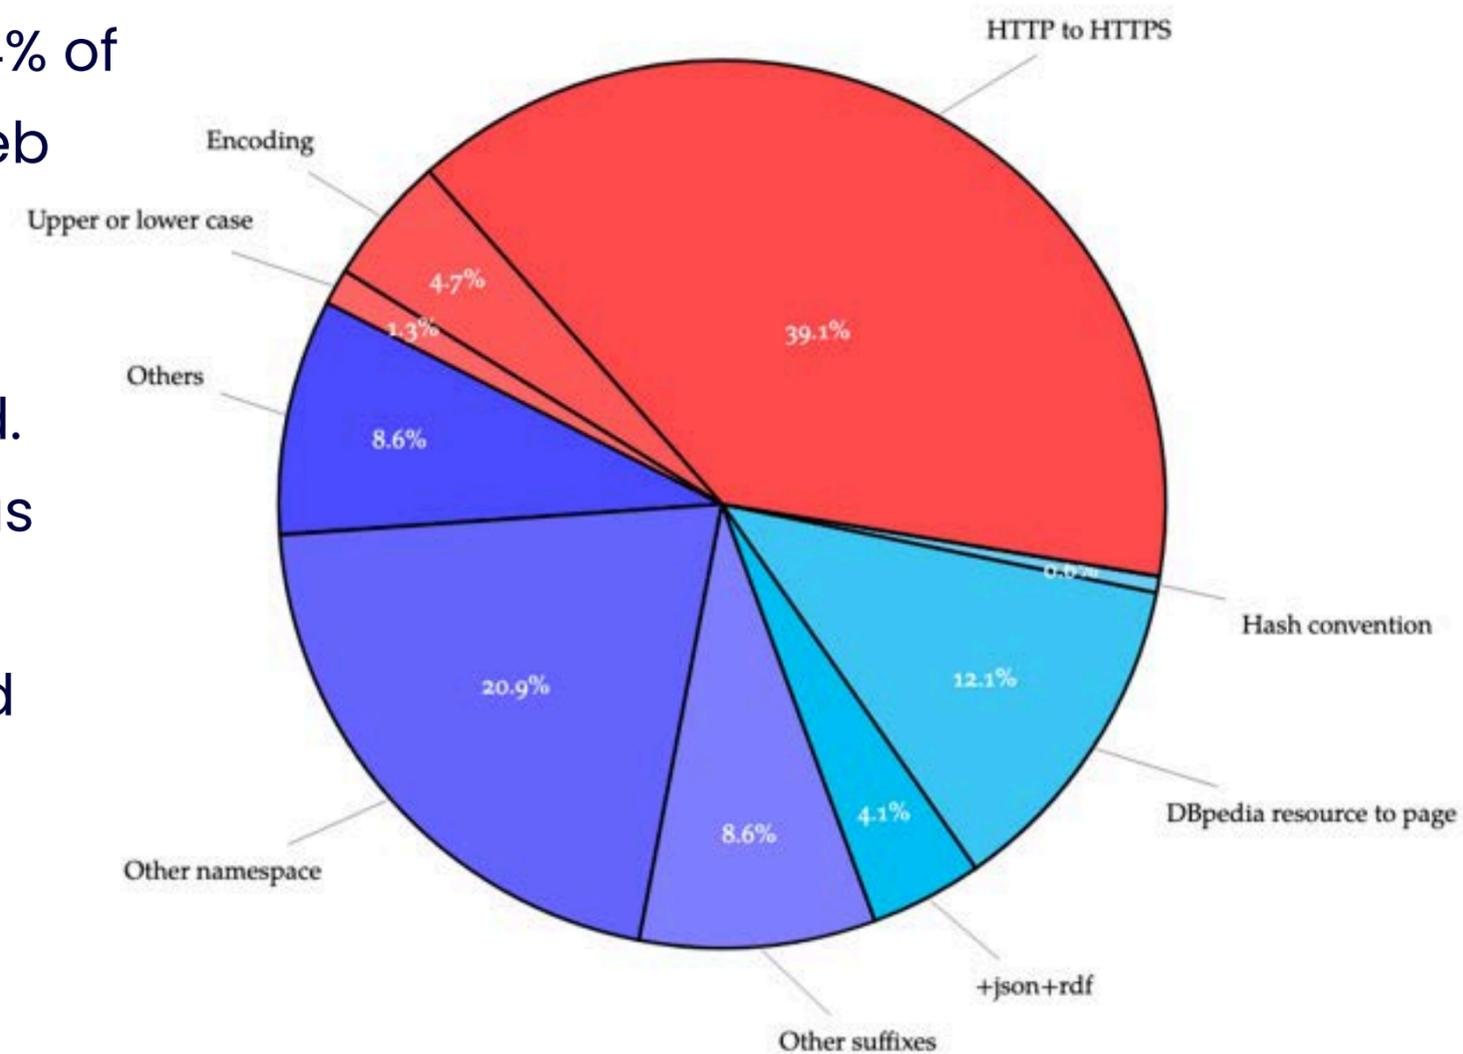

Figure 15: Proportion of redirection behavior among sampled entities

# TWO DOMAIN APPLICATIONS

- If not the biggest few KGs (e.g., DBpedia), would the problem be different?
- What happens if we limit the integrated KGs to some restricted domains?
- What are the **links** in the resulting integrated graphs like?
- What is the **scale** of the problem of refinement?
- Do they need some **new algorithms** for domain-specific problems?
- Integrating some knowledge graphs of selected domains to form a larger KG.

## Ch5: Links in Integrated KGs in Economics, Finance, and Banking

- More **skos:relatedMatch** and **skos:closeMatch** than **owl:sameAs**.
- A “large” connected component with **15** entities about the telephone system, telecommunications engineering, telecommunications, etc.
- Similar to the experiments before, larger clusters are more likely to have errors.
- Smaller and simpler. Possible for manual refinement because the entities represents concepts that are well defined.
- No cycle of rdfs:subClassOf found.
- No cycle with more than two entities for lkif-core:component, fro:divides20, and its inverse fro:divided\_by.

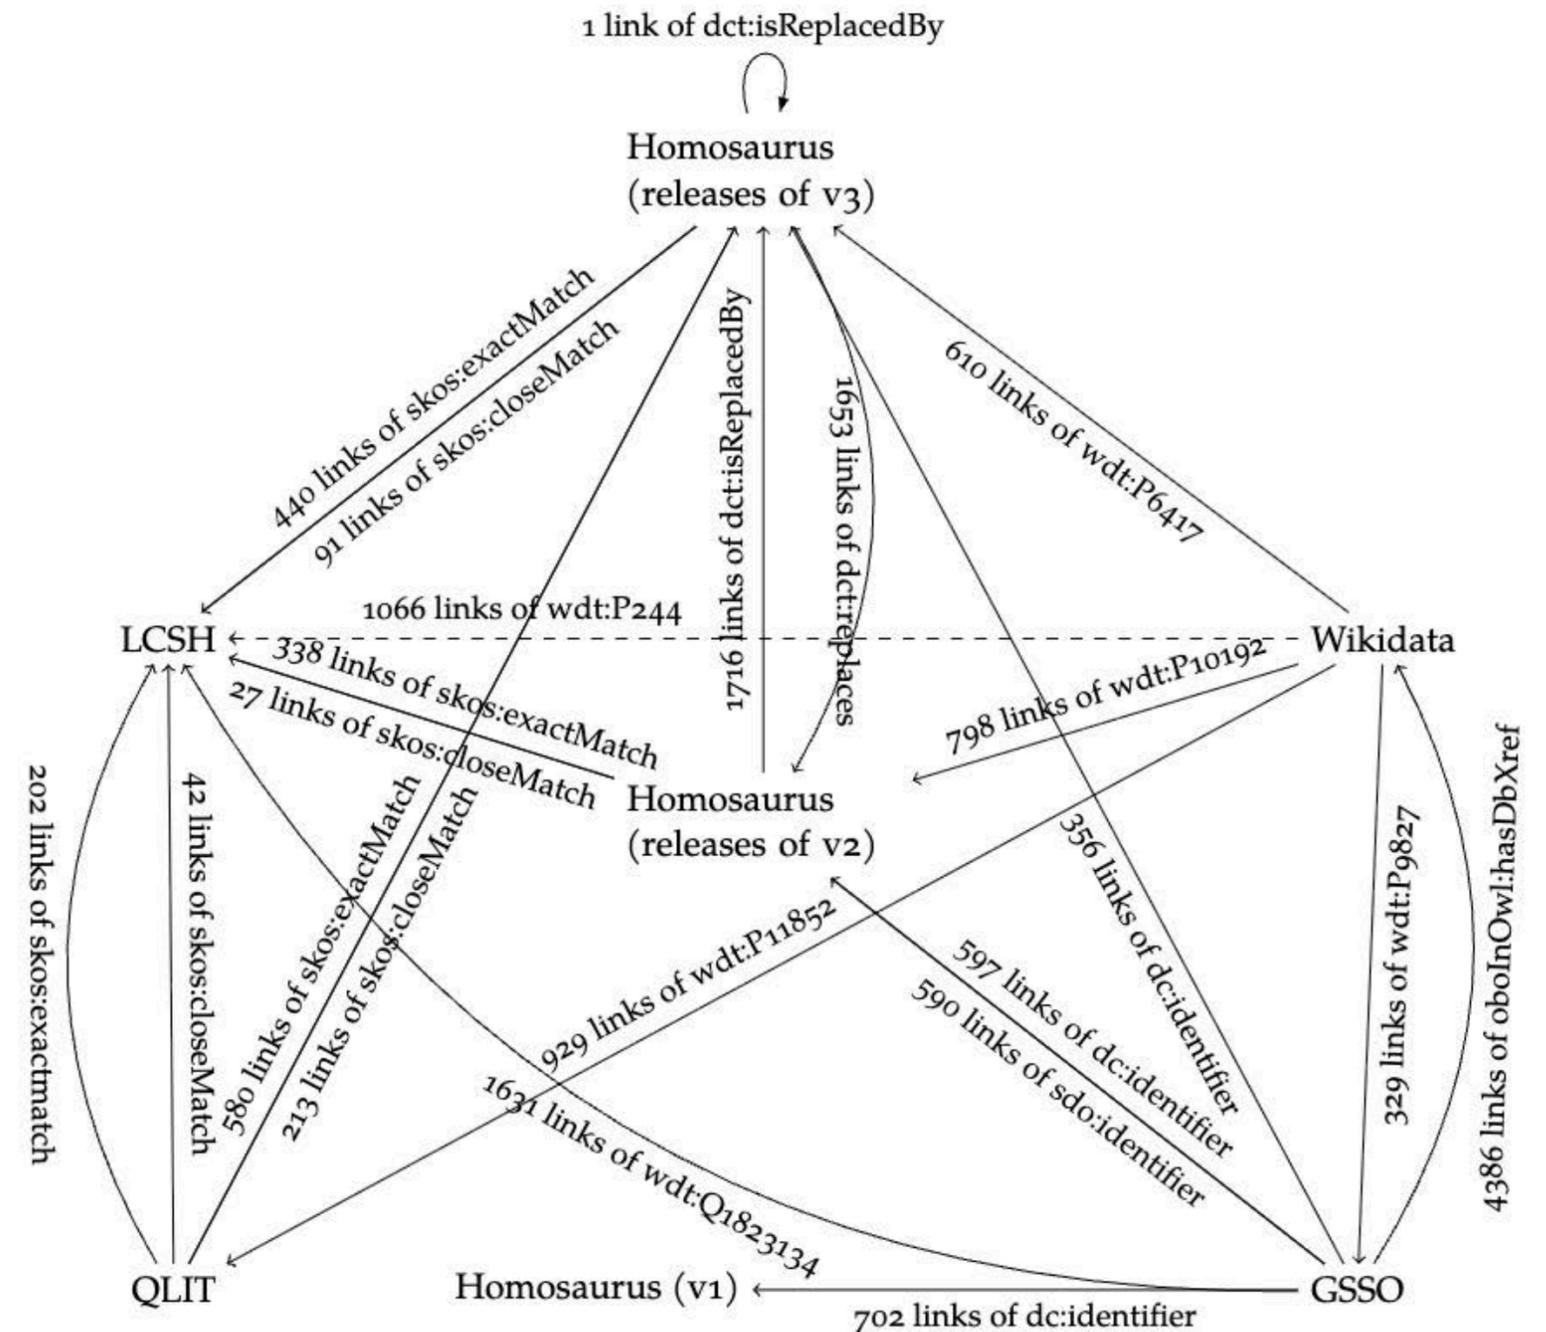

# Ch6: Examining LGBTQ+-related Concepts in the Semantic Web: Identity-related Link Discovery, Concept Change, Ambiguity, and Multilingual Information Enrichment

## KG construction

1. Relation extraction
  2. Refinement (wd:Q1823134->wdt:P244)
  3. Redirection
- skos:exactMatch/closeMatch
  - dc:identifier
  - dct:isReplacedBy/replaces
  - oboInOwl:hasDbXref
  - wdt:P6417/P10192/etc.
  - redirection (61+2): meta:redirectedTo
  - owl:sameAs

19.2K entities, 17.8K links.

6.4K WCCs. The largest WCCs are with 45, 36, 36, 35 entities, respectively.

# Ch6: Examining LGBTQ+-related Concepts in the Semantic Web: Identity-related Link Discovery, Concept Change, Ambiguity, and Multilingual Information Enrichment

## Scenario 1: Link Discovery

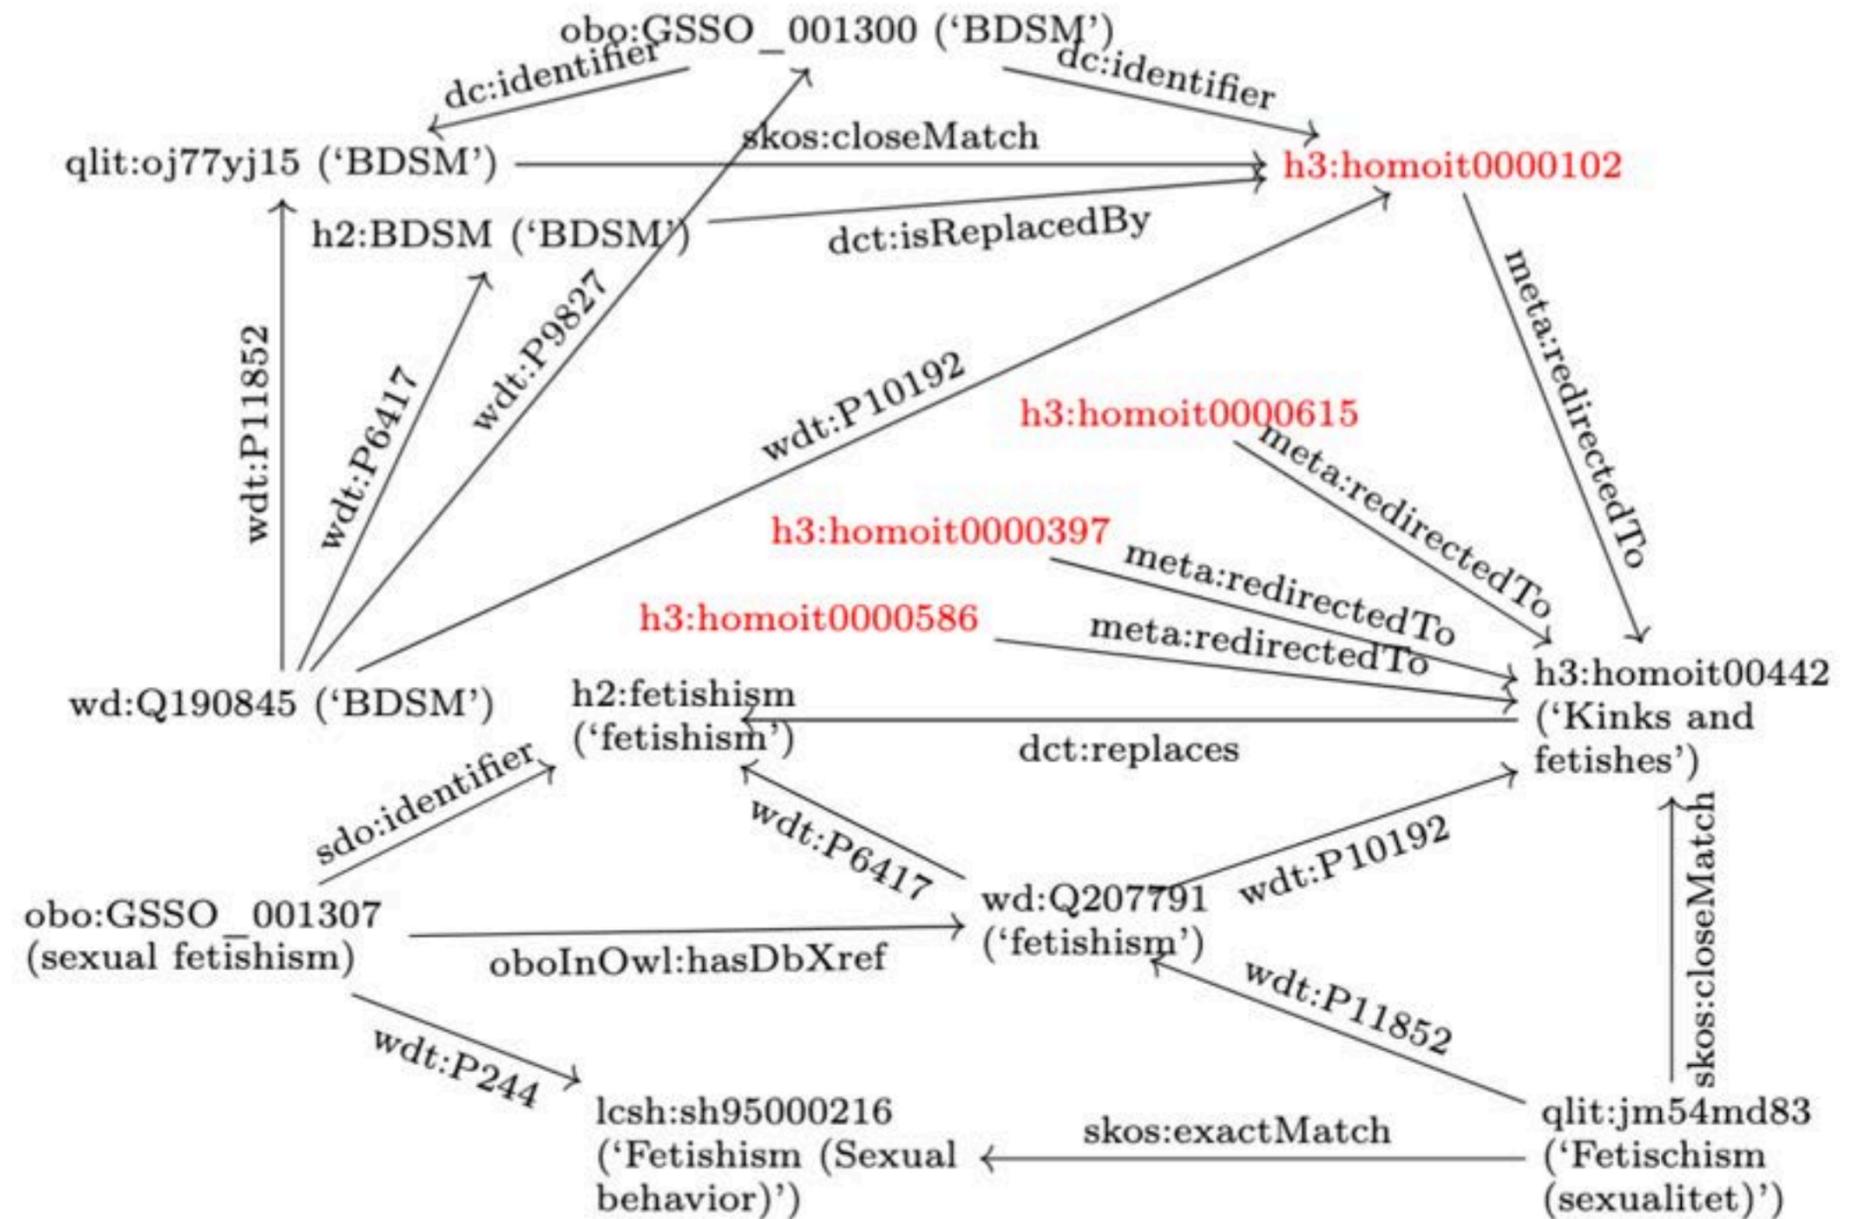

## Scenario 3: Multilingual Information Reuse

- Not to start from scratch when constructing a linked vocabulary of a given language
- Reuse multilingual labels from other resources (1-to-1 mapping)
- To not miss their alternative labels.

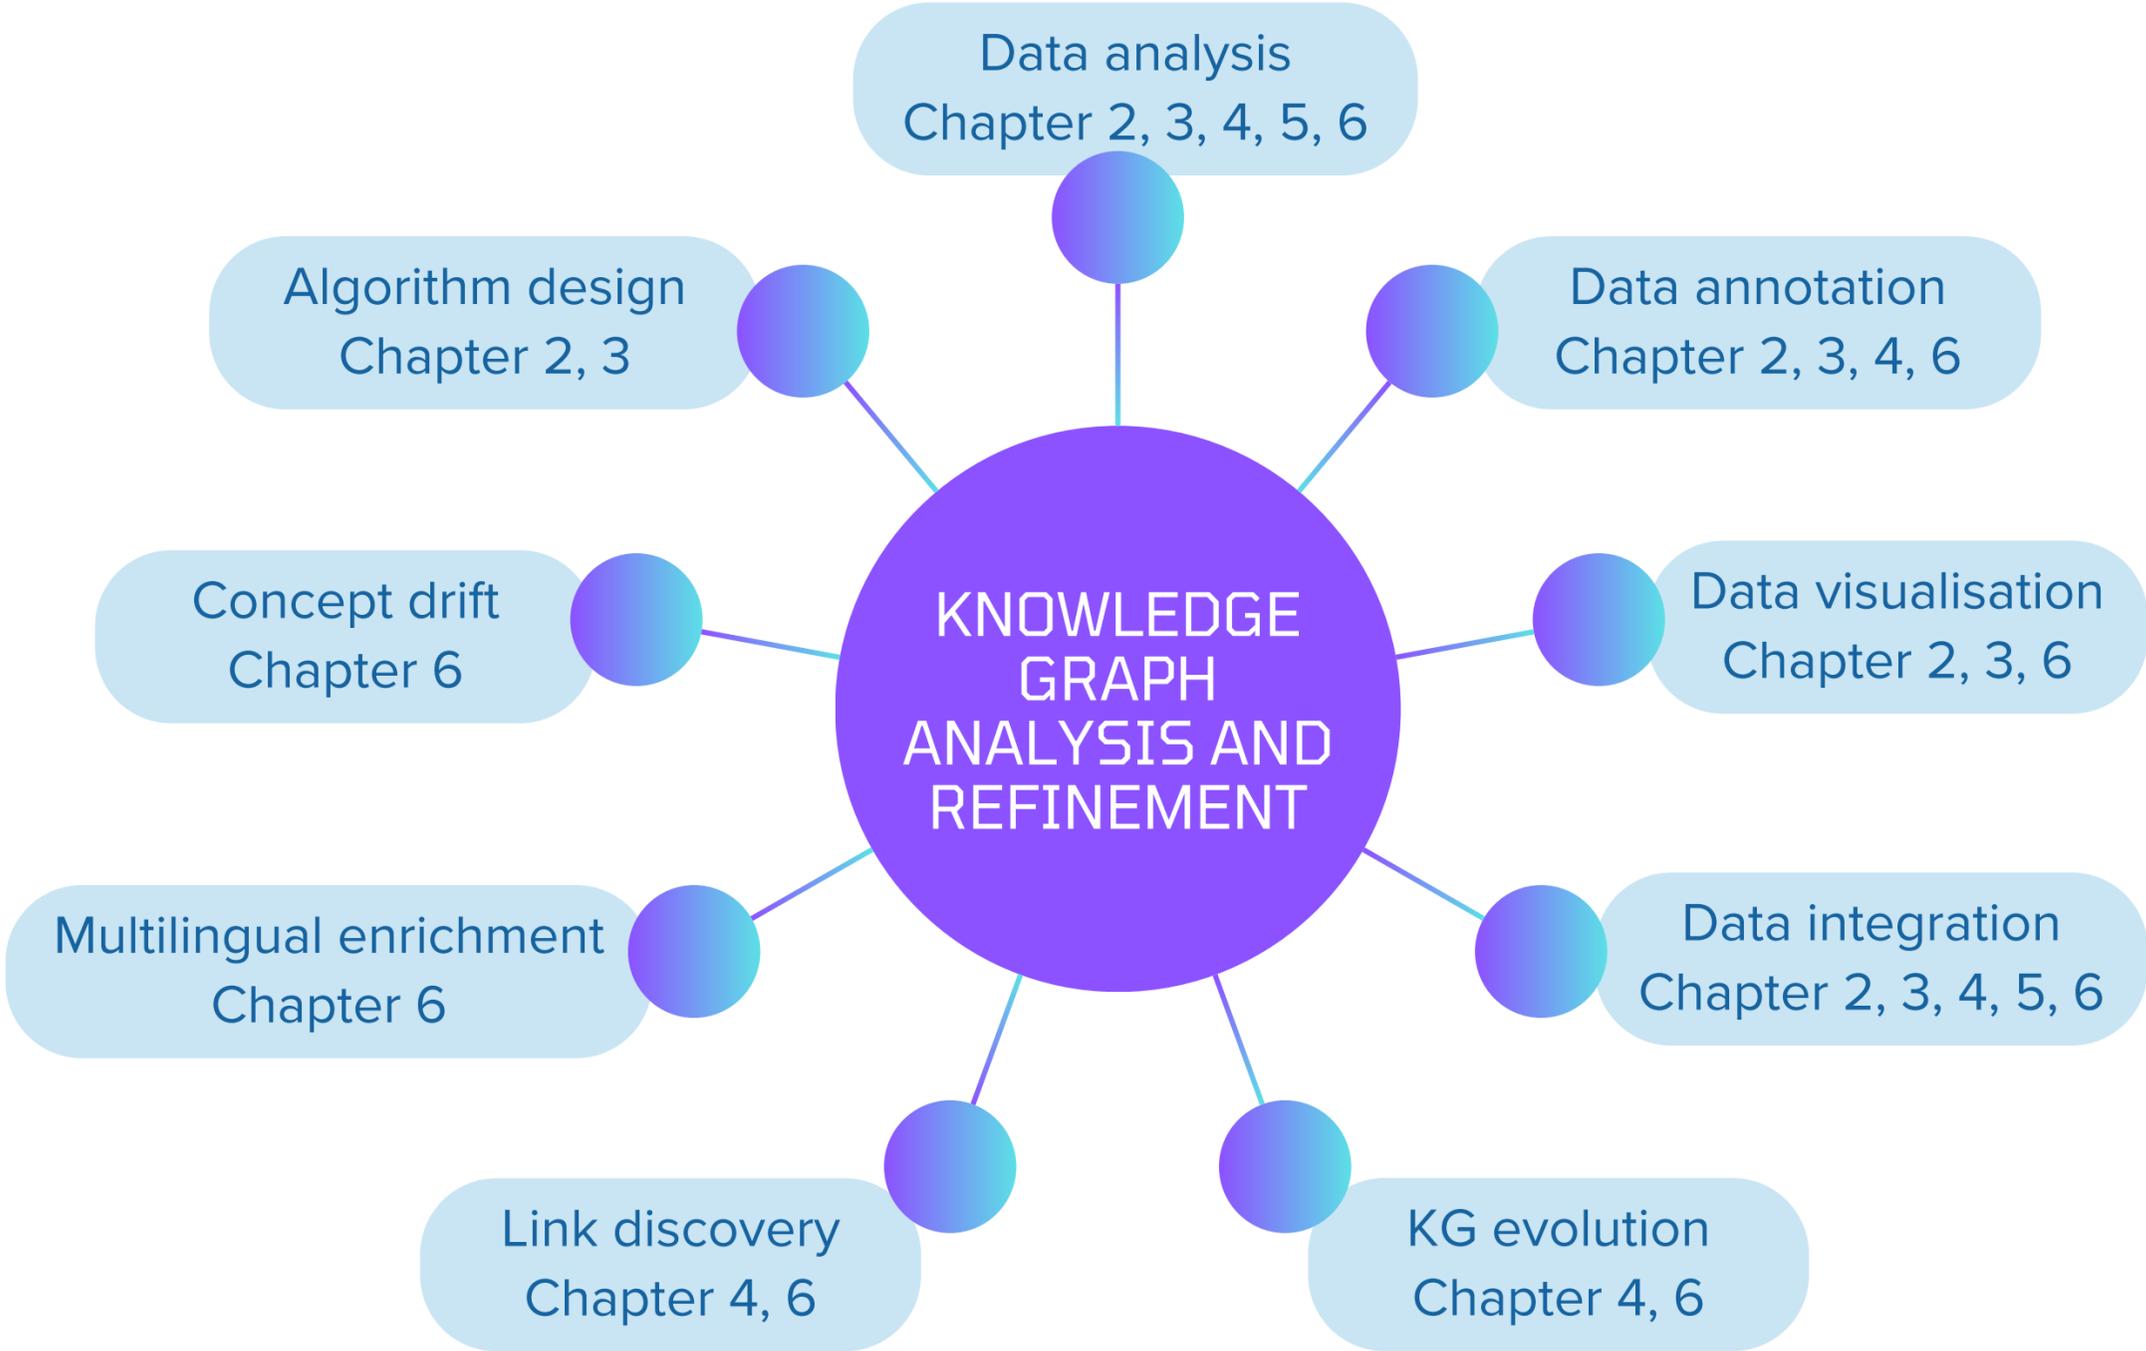

|                               | English | Spanish | Chinese | Portuguese | German |
|-------------------------------|---------|---------|---------|------------|--------|
| Number of labels              | 1,696   | 951     | 893     | 881        | 824    |
| Number of one-to-one mappings | 429     | 333     | 287     | 299        | 298    |
| Avg. labels per entity        | 3.94    | 2.86    | 3.11    | 2.95       | 2.77   |

## Scenario 2: Concept Drift and Change

*“elephant in the room”*

# Conclusion

# Thank you all!
